A Compositional Semantics for `eval` in Scheme

Listing of a Lightweight Agda Formalization

Peter D. Mosses

P.D.Mosses@tudelft.nl

Abstract

Scm is a simple sublanguage of Scheme; ScmQ adds quotations to Scm; and ScmQE adds `eval` expressions to ScmQ. An accompanying paper presents a denotational semantics of Scm, and the additions and changes to define the semantics of ScmQ and ScmQE.

This document provides a highlighted listing of the Agda source code of a lightweight formalization of the complete denotational semantics of ScmQE, and illustrates how soundness tests can be formulated and verified. For explanatory comments, see §6 of the accompanying paper.

Agda generated the LaTeX sources for the highlighted listing; a map from Unicode characters to similar-looking math symbols was manually coded. The LaTeX sources for the illustrative fragments presented in the body of the accompanying paper were copied from the Agda-generated sources, but may have been edited to adjust layout and alignment.

CCS Concepts: • **Theory of computation** → **Denotational semantics**; • **Software and its engineering** → **Semantics**; **Functional languages**.

Keywords: Scheme, denotational semantics, compositional semantics, quote and eval, Lisp, formalization, Agda
